

**AfNOG 2002**

The Exim Mail Transfer Agent

(A brief introduction)

**<http://www.exim.org>**

# Configuration file

- Exim uses a single runtime configuration file, which is divided into a number of sections
- The first section contains global option settings
- The other sections start with “begin *sectionname*”
- They are optional, and may appear in any order
- Comments, macros, and inclusions are available
- Option settings can refer to auxiliary data files, for example, a file of aliases (usually **/etc/aliases**)

## Changing the runtime configuration

- Edit **/usr/exim/configure** with your favourite text editor
- New Exim processes will pick up the new file right away
- You need to SIGHUP the daemon to restart it

```
kill -HUP `cat /var/spool/exim/exim-daemon.pid`
```

- Check the log to see if it restarted successfully

```
tail /var/spool/exim/log/mainlog
```

# Configuration file sections

- Global options
  - General and input-related options
- Address rewriting rules
  - Specify rewriting of envelope and header addresses
- Retry rules
  - Control retries after temporary failures
- Router configuration
  - Specify recipient address processing
- Transport configuration
  - Specify how actual deliveries are done
- Authenticator configuration
  - Specify SMTP authentication methods
- Access Control Lists (ACLs)
  - Define policy for incoming SMTP

# Default configuration file layout

Global option settings

- [ `begin ACL` ]
- [ Access control lists ]
- [ `begin routers` ]
- [ Router configuration ]
- [ `begin transports` ]
- [ Transport configuration ]
- [ `begin retry` ]
- [ Retry rules ]
- [ `begin rewrite` ]
- [ Rewriting rules ]
- [ `begin authenticators` ]
- [ Authenticator configuration ]

required for SMTP input

required for message delivery

# Examples of common global options

- SMTP input limits

```
smtp_accept_max = 200
```

```
smtp_accept_queue = 150
```

```
smtp_accept_reserve = 10
```

```
smtp_reserve_hosts = 192.168.0.0/16
```

```
smtp_connect_backlog = 100
```

- Overloading

```
queue_only_load = 5
```

```
deliver_queue_load_max = 7
```

- Message size limits

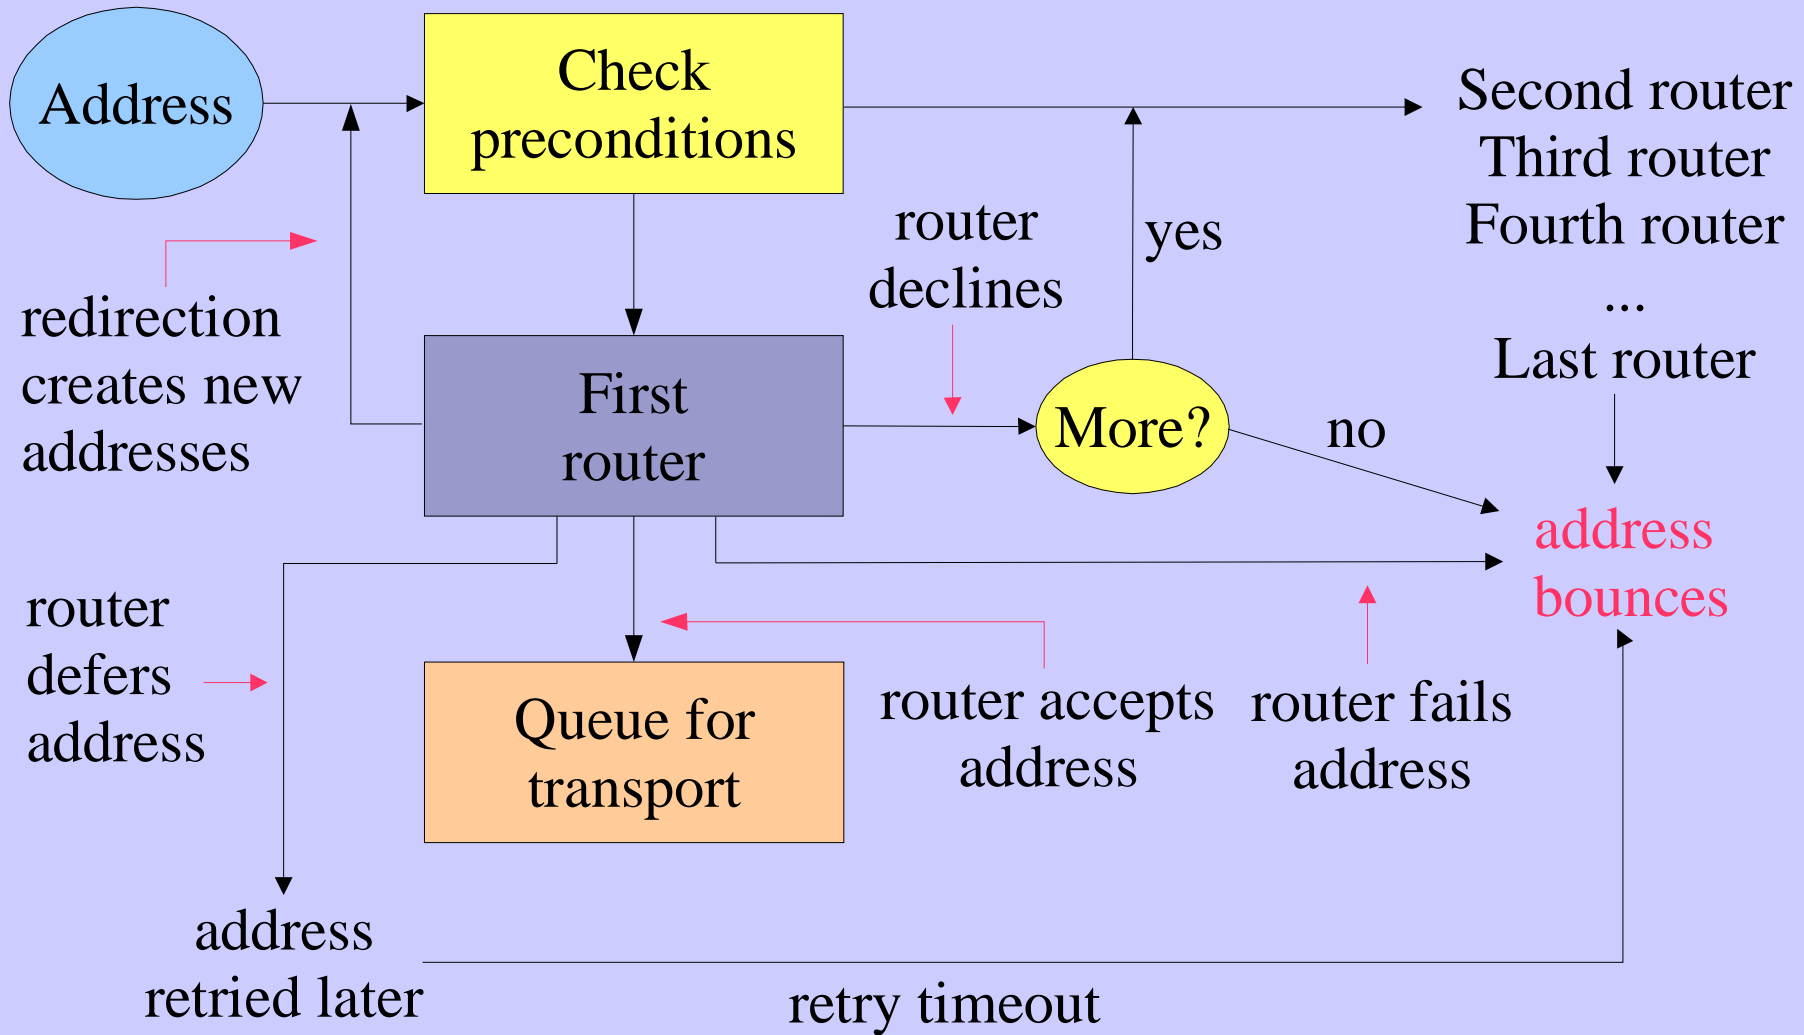

```
message_size_limit = 10M
```

```
return_size_limit = 65535
```

## Exim 4 routers

- Exim contains a number of different routers
  - Example: the *dnslookup* router does DNS processing
  - the *redirect* router does address redirection (aliasing and forwarding)
- The configuration defines which routers are used, in which order, and under what conditions
  - Example: routers are often restricted to specific domains
- The same router may appear more than once, usually with different configurations
- The order in which routers are defined matters

# Exim 4 routing

# Simple routing configuration

- Check for non-local domain: run *dnslookup* router
  - Accept: queue for smtp transport
  - Decline: “no\_more” set => address bounces
- Check for system aliases: *redirect* router
  - Accept: generates new address(es)
  - Decline: passed to next router
- Check for local user forwarding: another *redirect* router
  - Accept: generates new address(es)
  - Decline: passed to next router
- Check for local user: run *accept* router
  - Accept: queue for appendfile transport
- No more routers => address bounces

# Exim transports

- Transports are the components of Exim that actually deliver copies of messages
  - The *smtp* transport delivers over TCP/IP to a remote host
  - The *appendfile* transport writes to a local file
  - The *pipe* transport writes to another process via a pipe
  - The *lmtp* transport does likewise, using LMTP
  - The *autoreply* transport is anomalous, in that it creates an automatic response instead of doing a real delivery
- The order in which transports are defined is unimportant
- A transport is used only when referenced from a router
- Transports are run in subprocesses, under their own uid, after all routing has been done

# Default routers (1)

- The first router handles non-local domains

```
dnslookup:
```

```
driver = dnslookup
```

```
domains = ! +local_domains
```

```
ignore_target_hosts = 127.0.0.0/8
```

```
transport = remote_smtp
```

```
no_more
```

- The precondition checks for a nonlocal domain
- Silly DNS entries are ignored
- If the domain is found in the DNS, queue for **remote\_smtp**
- Otherwise, **no\_more** changes “decline” into “fail”

## Default routers (2)

- The second router handles system aliases

```
system_aliases:  
  driver = redirect  
  data = ${lookup{$local_part}lsearch\  
         {/etc/aliases}}  
  
  allow_fail                allows :fail:  
  allow_defer               allows :defer:  
  
  pipe_transport = address_pipe  
  file_transport = address_file  
  user = exim
```

- Alias file lines look like this

```
postmaster:  pat, james@otherdom.example  
retired:    :fail: No longer works here  
majordomo:  |/usr/bin/majordom ...
```

## Default routers (3)

- The third router handles users' *.forward* files

userforward:

```
driver = redirect
```

```
check_local_user
```

```
file = $home/.forward
```

```
no_verify
```

```
pipe_transport = address_pipe
```

```
file_transport = address_file
```

```
reply_transport = address_reply
```

```
allow_filter
```

- **data** and **file** are mutually exclusive options for **redirect**

**data** expands to a redirection list

**file** expands to the name of a file containing such a list

## Default routers (4)

- The final router handles local user's mailboxes

```
localuser:  
  driver = accept  
  check_local_user  
  transport = local_delivery
```

- Recap - an address is routed like this:

Remote address	=> <b>remote_smtp</b> transport
System alias	=> new address(es), fail, defer
User's <i>.forward</i>	=> new address(es)
Local user	=> <b>local_delivery</b> transport
Unrouteable address	=> bounce

- This is just one out of many possible configurations

# Default transports (1)

- Main transports

```
remote_smtp:  
    driver = smtp
```

```
local_delivery:  
    driver = appendfile  
    file = /var/mail/$local_part  
    delivery_date_add  
    return_path_add  
    envelope_to_add  
    # group = mail  
    # mode = 0660
```

- Default assumes a “sticky bit” directory

Setting **group** and **mode** is an alternate approach

## Default transports (2)

- Auxiliary transports

```
address_pipe:  
  driver = pipe  
  return_output
```

```
address_file:  
  driver = appendfile  
  delivery_data_add  
  return_path_add  
  envelope_to_add
```

```
address_reply:  
  driver = autoreply
```

# Routing to smarthosts

- Replace the first router with this

```
send_to_smarthost:  
  driver = manualroute  
  domains = ! +local_domains  
  route_list = * smart-host1.example:\  
               smart-host2.example  
  transports = route_smtp
```

- A **route\_list** rule contains three space-separated items
  - The first is a domain pattern: \* matches any domain
  - The second is a list of hosts for the matching domains
  - The third is **byname** (default) or **bydns**
- Set **hosts\_randomize** to sort the hosts randomly each time

# Virtual domains

- Straightforward cases are just aliasing

```
virtual_domains:  
    driver = redirect  
    domains = lsearch;/etc/virtuals  
    data = ${lookup{$local_part}lsearch\  
           {/etc/aliases-$domain}}  
    no_more
```

- An alias with no domain assumes the local qualify domain

```
philip:    ph10  
jc:       julius@other.domain.com
```

## Access control lists

- ACLs are relevant only for SMTP input  
But they do apply to local SMTP (**-bs** and **-bS**)
- For incoming SMTP messages
  - acl\_smtp\_rcpt** defines the ACL to be run for each RCPT  
Default is “deny”
  - acl\_smtp\_data** defines the ACL to be run after DATA  
Default is “accept”
- Tests on message content can only be done after DATA
- Other ACLs can be used for AUTH, ETRN, EXPN, VRFY

# A simple ACL

```
acl_smtp_rcpt = acl_check_rcpt
```

```
begin acl
```

```
acl_check_rcpt:
```

```
    accept    local_parts = postmaster  
            domains      = +my_domains
```

```
    require  verify      = sender
```

```
    accept  domains      = +my_domains  
            verify      = recipient
```

- Implicit “deny” at the end

## Named item lists

```
domainlist local_domains = @ : plc.com
hostlist   relay_hosts   = 192.168.32.0/24
```

- Abstraction: list is specified in one place only  
References are shorter and easier to understand
- Optimization: matches in named lists are cached  
Example: several routers testing the same domain list
- A named list is referenced by prefixing its name with +  

```
hosts = 127.0.0.1 : +relay_hosts
```
- A named list can be negated  

```
domains = !+local_domains
```

  
This is not possible with macros

# ACL statements

- Each statement contains a verb and a list of conditions

*verb*    *condition 1*                      (one per line)  
          *condition 2*  
          ...

- If all the conditions are satisfied

**accept**    Allows the SMTP command to proceed (else may pass or reject - see next slide)

**deny**      Rejects (else passes)

**require**   Passes (else rejects)

**warn**      Takes some warning action (e.g. logs or adds header)  
              Always passes

# ACL modifiers

- **message** defines a custom message for a denial or warning

```
deny    message    = You are black listed at \  
                    $dnslist_domain  
dnslists = rbl.mail-abuse.org : ...
```

- **log\_message** defines a custom log message

```
require log_message = Recipient verify failed  
verify    = recipient
```

- **endpass** is used with the **accept** verb for a 3-way outcome

```
accept domains = +local_domains  
endpass  
verify    = recipient
```

Above **endpass**, failure causes the next statement to be run

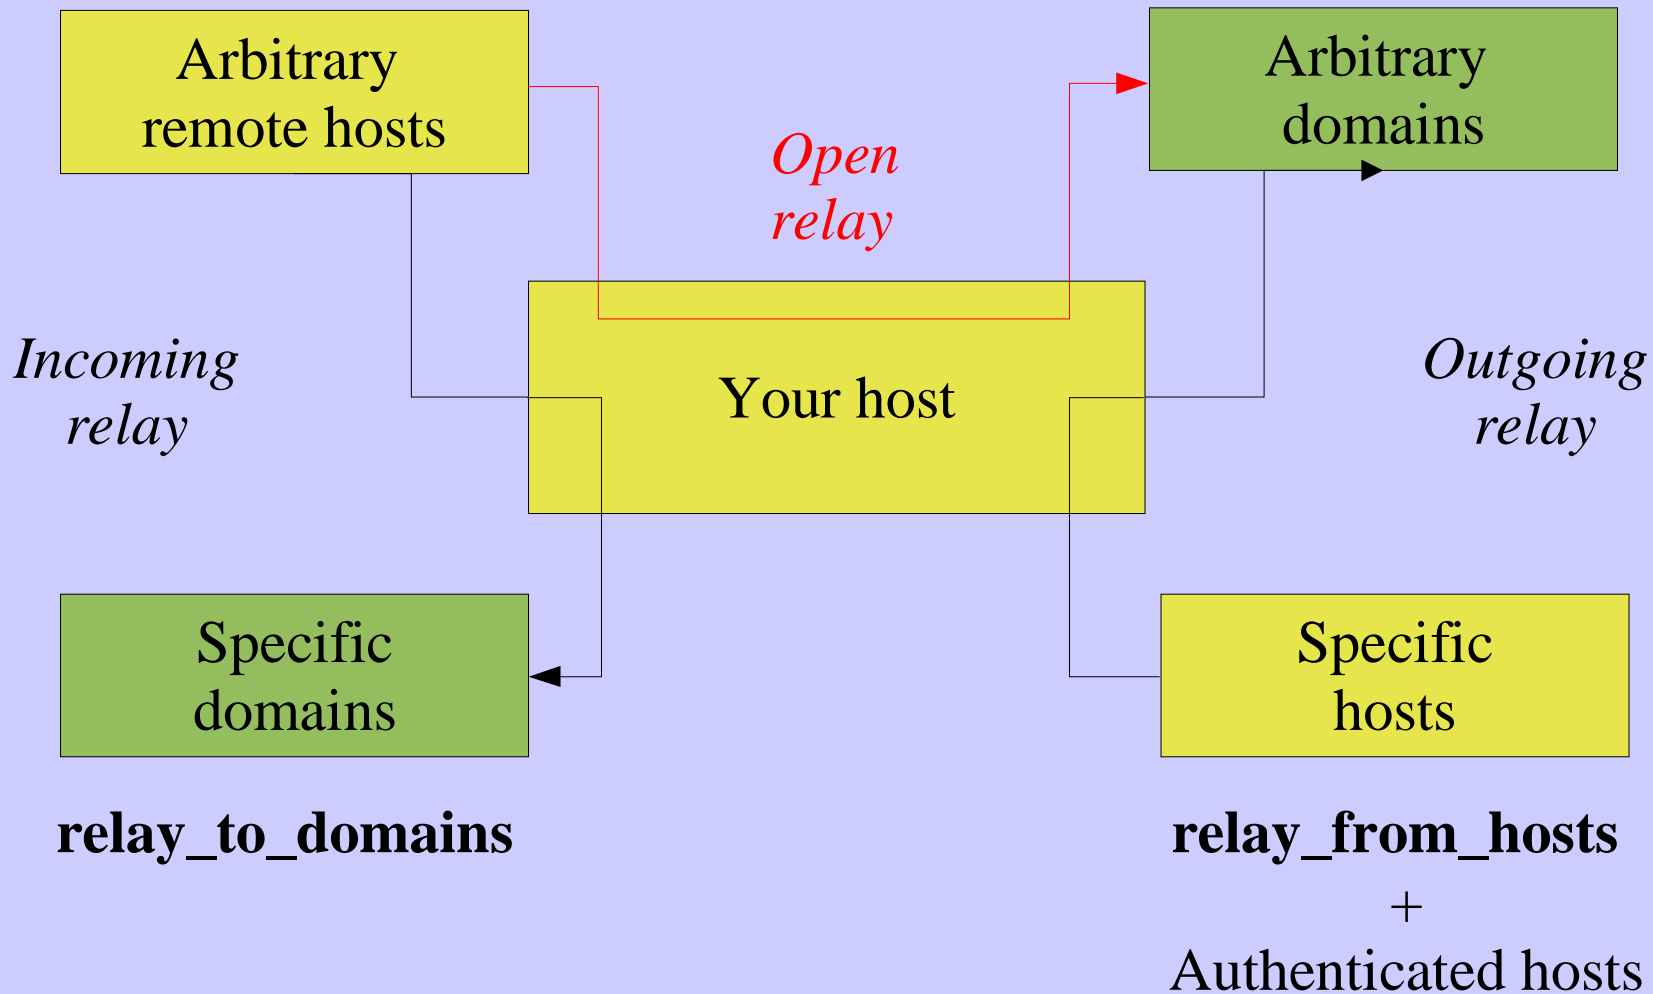

Below **endpass**, failure causes rejection

## The default ACL

```
acl_check_rcpt:
  accept  hosts          = :
  deny    local_parts    = ^.*[!@%|/]
  accept  local_parts    = postmaster
          domains        = +local_domains
  require verify        = sender
  accept  domains        = +local_domains
          endpass
          message         = unknown user
          verify          = recipient
  accept  domains        = +relay_to_domains
          endpass
          message         = unrouteable address
          verify          = recipient
  accept  hosts          = +relay_from_hosts
  accept  authenticated   = *
  deny    message         = relay not permitted
```

# Good and bad relaying

# Message filtering

- Exim supports three kinds of filtering
  - User filter: run while routing (“*.forward with conditions*”)
  - System filter: run once per message
  - Transport filter: external program added to transport
- User and system filters are run for each delivery attempt
  - If delivery is deferred, filters run more than once
- User and system filters use the same syntax
  - System filter has some additional commands (**fail**, **freeze**)
  - They can be enabled for redirection filters
- Exim also supports a *local\_scan()* function
  - Local C code can inspect a message at the point of arrival

# User filter example

```
# Exim filter
# Don't touch bounces
if error_message then finish endif
# Throw away junk
if
    $h_subject: contains "Make money" or
    $sender_address matches \N^\d{8}@\N or
    $message_body contains "this is spam"
then seen finish endif
# Auto-reply
if personal alias ph10@cam.ac.uk then
    mail subject "Re: $h_subject:"
    file $home/auto-reply/message
    log $home/auto-reply/log
    once $home/auto-reply/once
endif
```

## Filter commands

- **deliver** does “true” forwarding (sender does not change)
- **save** delivers to a named file
- **pipe** delivers via a pipe to a given command
- **mail** generates a new mail message
- **logwrite** writes to a log file
  
- **deliver**, **save**, and **pipe** are significant by default
  - Can be made not significant by **unseen**
- **logwrite** happens during filtering
- The others are just set up during filtering and happen later
  - The result of **pipe** is not available during filtering
  
- Sysadmin can lock out a number of filter facilities
  - **save**, **pipe**, **mail**, and **logwrite** commands
  - existence tests, lookups, Perl, readfile, run in expansions

# The system filter

- Runs once per message, at every delivery start
  - Use **first\_delivery** to detect very first time
  - Can see all recipients in **\$recipients**
- Can add to recipients or completely replace recipients
  - Non-significant delivery adds, significant delivery replaces
- Can add header lines that are visible to the routers, transports, and user filters
- Can remove header lines
- Can freeze message or bounce it
- Set up by

```
system_filter = /etc/exim/sysfilter
system_filter_file_transport = address_file
system_filter_pipe_transport = address_pipe
system_filter_user = exim
```

# Large installations

- Use a local name server with plenty of memory
- Exim is limited by disc I/O
  - Use fast disc hardware
  - Put hints on RAM disc
  - Set **split\_spool\_directory**
  - Use multiple directories for user mailboxes
- Avoid linear password files
- Use maildir format to allow parallel deliveries
- Plan to expand “sideways” with parallel servers
  - This also helps add more disc access capacity
- Separate incoming and outgoing mail
- Keep output queue as short as possible
  - Use fallback hosts and/or **\$message\_age** for several levels

# Separating mail functions
