Introduction to ISIS

AfNOG 2011 AR-E Workshop

IS-IS Standards History

- ISO 10589 specifies OSI IS-IS routing protocol for CLNS traffic
 - A Link State protocol with a 2 level hierarchical architecture
 - Type/Length/Value (TLV) options to enhance the protocol
- RFC 1195 added IP support
 - Integrated IS-IS
 - I/IS-IS runs on top of the Data Link Layer
 - Requires CLNP to be configured
- RFC5308 adds IPv6 address family support to IS-IS
- RFC5120 defines Multi-Topology concept for IS-IS
 - Permits IPv4 and IPv6 topologies which are not identical
 - (Required for an incremental roll-out of IPv6 on existing IPv4 infrastructure)

ISIS Levels

ISIS has a 2 layer hierarchy

- Level-2 (the backbone)
- Level-1 (the areas)

A router can be

- Level-1 (L1) router
- Level-2 (L2) router
- Level-1-2 (L1L2) router

ISIS Levels

Level-1 router

- Has neighbours only on the same area
- Has a level-1 LSDB with all routing information for the area

Level-2 router

- May have neighbours in the same or other areas
- Has a Level-2 LSDB with all routing information about inter-area
- Level-1-2 router
 - May have neighbours on any area.
 - Has two separate LSDBs: level-1 LSDB & level-2 LSDB

Backbone & Areas

- ISIS does not have a backbone area as such (like OSPF)
- Instead the backbone is the contiguous collection of Level-2 capable routers
- ISIS area borders are on links, not routers
- Each router is identified with a unique Network Entity Title (NET)
 - NET is a Network Service Access Point (NSAP) where the n-selector is 0
 - (Compare with each router having a unique Router-ID with IP routing protocols)

L1, L2, and L1L2 Routers

NSAP and Addressing

NSAP: Network Service Access Point

- Total length between 8 and 20 bytes
- Area Address: variable length field (up to 13 bytes)
- System ID: defines an ES or IS in an area.
- NSEL: N-selector. identifies a network service user (transport entity or the IS network entity itself)
- NET: the address of the network entity itself

An Addressing Example

Addressing Common Practices

ISPs typically choose NSAP addresses thus:

- First 8 bits pick a number (usually 49)
- Next 16 bits area
- Next 48 bits router loopback address
- Final 8 bits zero

Example:

- NSAP: 49.0001.1921.6800.1001.00
- Router: 192.168.1.1 (loopback) in Area 1

Addressing & Design Practices

ISPs usually only use one area

- Multiple areas only come into consideration once the network is several hundred routers big
- NET begins with 49
 - "Private" address range
- All routers are in L2 only
 - Note that Cisco IOS default is L1L2
 - Set L2 under ISIS generic configuration (can also be done per interface)

Adjacencies

Hello Protocol Data Units (PDUs) are exchanged between routers to form adjacencies

- Area addresses are exchanged in IIH PDUs
 - Intermediate-System to Intermediate System Hello PDUs
 - (PDU is ISIS equivalent of a packet)

Link State PDU (LSP)

- Each router creates an LSP and floods it to neighbours
- A level-1 router will create level-1 LSP(s)
- A level-2 router will create level-2 LSP(s)
- □ A level-1-2 router will create
 - level-1 LSP(s) and
 - level-2 LSP(s)

The ISIS LSP

- LSPs have a Fixed Header and TLV coded contents
- The LSP header contains
 - LSP-id Sequence number

Checksum

- Remaining Lifetime
- Type of LSP (level-1, level-2)
- Attached bitOverload bit
- The LSP contents are coded as TLV (Type, Length, Value)
 - Area addresses
 - IS neighbours
 - Authentication Information

Link State Database Content

Each router maintains a separate LSDB for level-1 and level-2 LSPs

- The LSDB contains:
 - LSP headers and contents
 - SRM bits: set per interface when router has to flood this LSP
 - SSN bits: set per interface when router has to send a PSNP for this LSP

Flooding of LSPs

New LSPs are flooded to all neighbors

All routers get all LSPs

Each LSP has a sequence number

There are 2 kinds of flooding:

- Flooding on a p2p link
- Flooding on LAN

Flooding on a p2p link

- Once the adjacency is established both routers send CSNP packet
- Missing LSPs are sent by both routers if not present in the received CSNP
- Missing LSPs may be requested through PSNP

Flooding on a LAN

Each LAN has a Designated Router (DIS)
The DIS has two tasks

- Conducting the flooding over the LAN
- Creating and updating a special LSP describing the LAN topology (Pseudonode LSP)

DIS election is based on priority

- Best practice is to select two routers and give them higher priority – then in case of failure one provides deterministic backup for the other
- Tie break is by the highest MAC address

Flooding on a LAN

DIS conducts the flooding over the LAN
DIS multicasts CSNP every 10 seconds
All routers on the LAN check the CSNP against their own LSDB (and may ask specific re-transmissions with PSNPs)

Complete Sequence Number PDU

- Describes all LSPs in your LSDB (in range)
- If the LSDB is large, multiple CSNPs are sent
- Used on 2 occasions:
 - Periodic multicast by DIS (every 10 seconds) to synchronise the LSDB over LAN subnets
 - On p2p links when link comes up

Partial Sequence Number PDUs

- PSNPs Exchanged on p2p links (ACKs)
- Two functions
 - Acknowledge receipt of an LSP
 - Request transmission of latest LSP
- PSNPs describe LSPs by its header
 - LSP identifier
 - Sequence number
 - Remaining lifetime
 - LSP checksum

Network Design Issues

- As in all IP network designs, the key issue is the addressing lay-out
- ISIS supports a large number of routers in a single area
- When network is so large requiring the use of areas, use summary-addresses
- >400 routers in the backbone is quite doable

Network Design Issues

Link cost

- Default on all interfaces is 10
- (Compare with OSPF which sets cost according to link bandwidth)
- Manually configured according to routing strategy
- Summary address cost
 - Equal to the best more specific cost
 - Plus cost to reach neighbor of best specific
- Backbone has to be contiguous
 - Ensure continuity by redundancy
- Area partitioning
 - Design so that backbone can NOT be partitioned

Scaling Issues

Areas vs. single area

- Use areas where
 - sub-optimal routing is not an issue
 - areas with one single exit point

Start with L2-only everywhere

- Future implementation of level-1 areas will be easier
- Backbone continuity is ensured from start

Typical ISP Design
