Introduction to BGP

ISP Workshops

Border Gateway Protocol

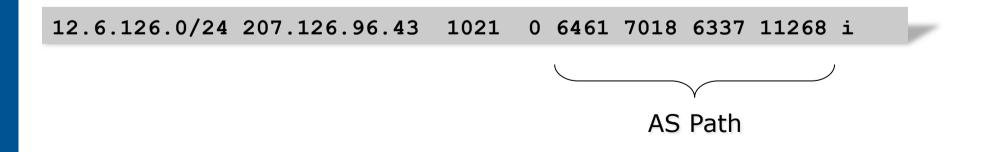

- A Routing Protocol used to exchange routing information between different networks
 - Exterior gateway protocol
- Described in RFC4271
 - RFC4276 gives an implementation report on BGP
 - RFC4277 describes operational experiences using BGP
- The Autonomous System is the cornerstone of BGP
 - It is used to uniquely identify networks with a common routing policy

BGP

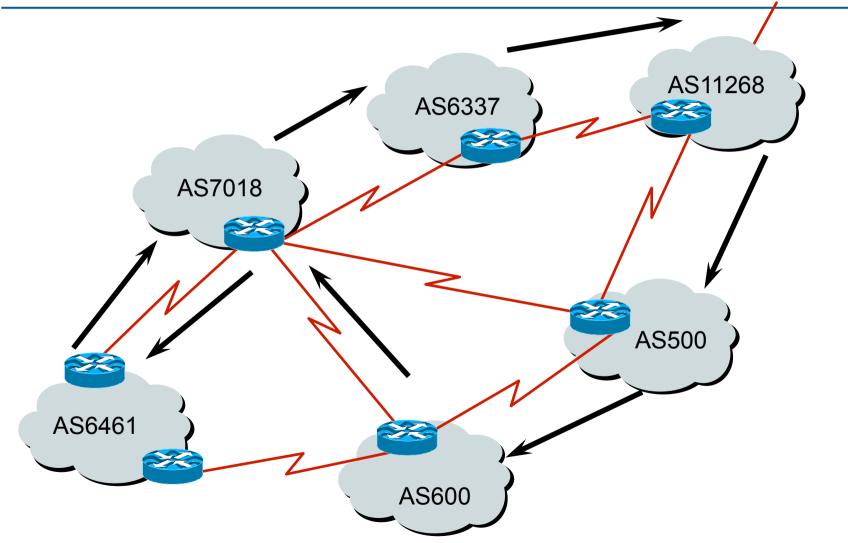

Path Vector Protocol
 Incremental Updates
 Many options for policy enforcement
 Classless Inter Domain Routing (CIDR)
 Widely used for Internet backbone
 Autonomous systems

Path Vector Protocol

- BGP is classified as a *path vector* routing protocol (see RFC 1322)
 - A path vector protocol defines a route as a pairing between a destination and the attributes of the path to that destination.

Path Vector Protocol

Definitions

Transit – carrying traffic across a network

- (Commercially: for a fee)
- Peering exchanging routing information and traffic
 - (Commercially: between similar sized networks, and for no fee)

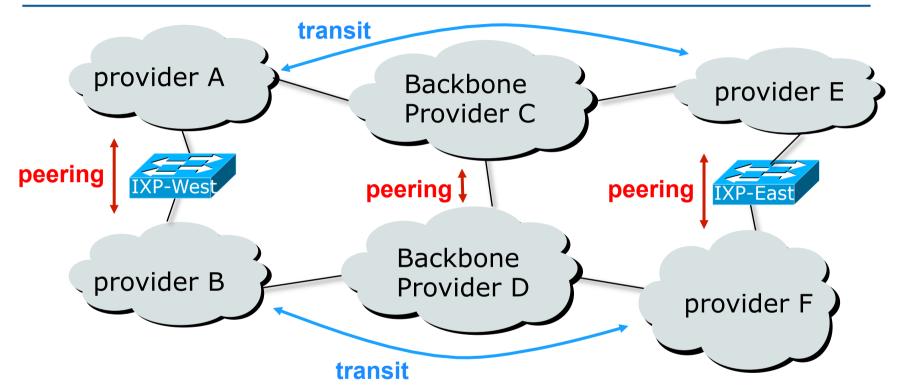

Default – where to send traffic when there is no explicit match in the routing table

Default Free Zone

The default free zone is made up of Internet routers which have routing information about the whole Internet, and therefore do not need to use a default route

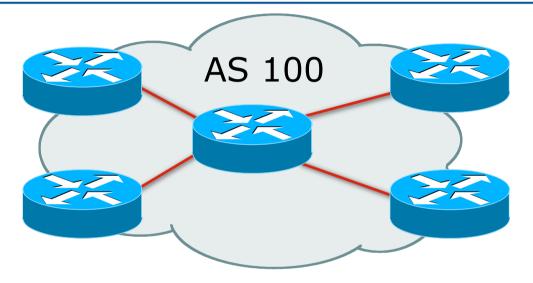

NB: is not related to where an ISP is in the hierarchy

Peering and Transit example

A and B peer for free, but need transit arrangements with C and D to get packets to/from E and F

Autonomous System (AS)

- Collection of networks with same routing policy
- Single routing protocol
- Usually under single ownership, trust and administrative control
- Identified by a unique 32-bit integer (ASN)

Autonomous System Number (ASN)

- Two ranges 0-65535 (original 16-bit range) (32-bit range – RFC6793) 65536-4294967295 □ Usage: 0 and 65535 (reserved) (public Internet) 1-6449564496-64511 (documentation – RFC5398) 64512-65534 (private use only) (represent 32-bit range in 16-bit world) 23456 (documentation – RFC5398) 65536-65551 65552-4199999999 (public Internet) 420000000-4294967295 (private use only - RFC6996)
- 32-bit range representation specified in RFC5396
 - Defines "asplain" (traditional format) as standard notation

Autonomous System Number (ASN)

- ASNs are distributed by the Regional Internet Registries
 - They are also available from upstream ISPs who are members of one of the RIRs
- Current 16-bit ASN assignments up to 64297 have been made to the RIRs
 - Around 50200 are visible on the Internet
 - Around 200 left unassigned
- Each RIR has also received a block of 32-bit ASNs
 - Out of 9300 assignments, around 7200 are visible on the Internet
- See www.iana.org/assignments/as-numbers

Configuring BGP in Cisco IOS

This command enables BGP in Cisco IOS: router bgp 100

For ASNs > 65535, the AS number can be entered in either plain or dot notation:

router bgp 131076

Or

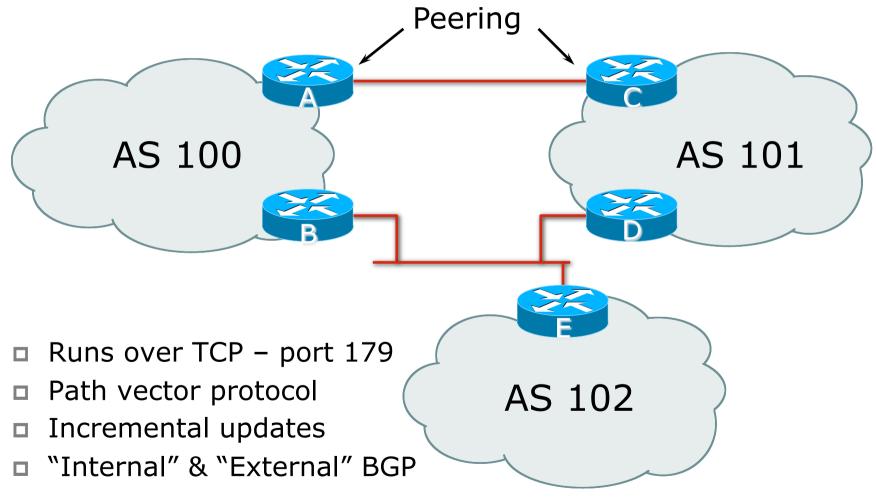

router bgp 2.4

IOS will display ASNs in plain notation by default

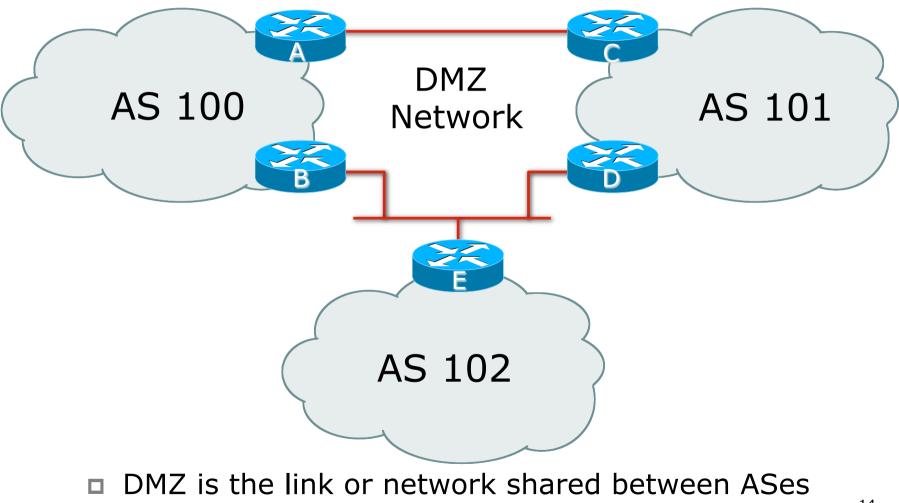

Dot notation is optional:

router bgp 2.4 bgp asnotation dot

BGP Basics

Demarcation Zone (DMZ)

BGP General Operation

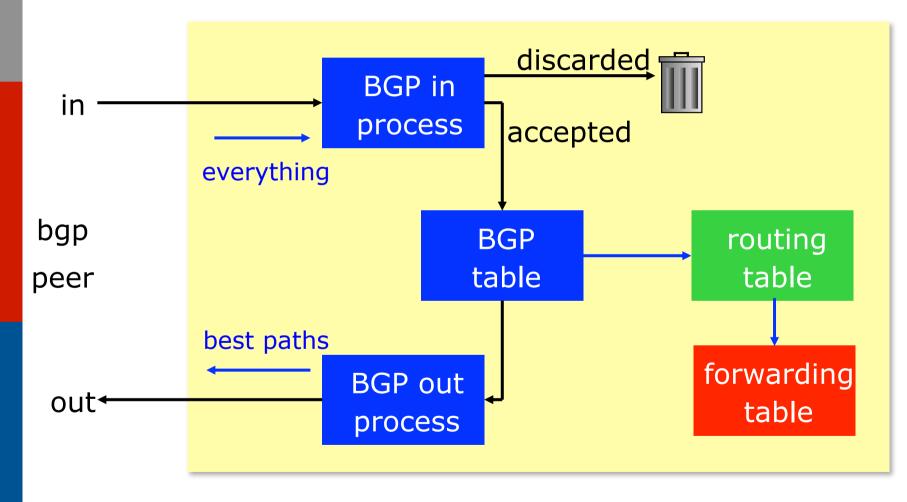

- Learns multiple paths via internal and external BGP speakers
- Picks the best path and installs it in the routing table (RIB)
- Best path is sent to external BGP neighbours
- Policies are applied by influencing the best path selection

Constructing the Forwarding Table

■ BGP "in" process

- Receives path information from peers
- Results of BGP path selection placed in the BGP table
- "best path" flagged
- BGP "out" process
 - Announces "best path" information to peers
- Best path stored in Routing Table (RIB) if:
 - Prefix and prefix length are unique, and
 - Lowest "protocol distance"
- Best paths in the RIB are installed in forwarding table (FIB)

Constructing the Forwarding Table

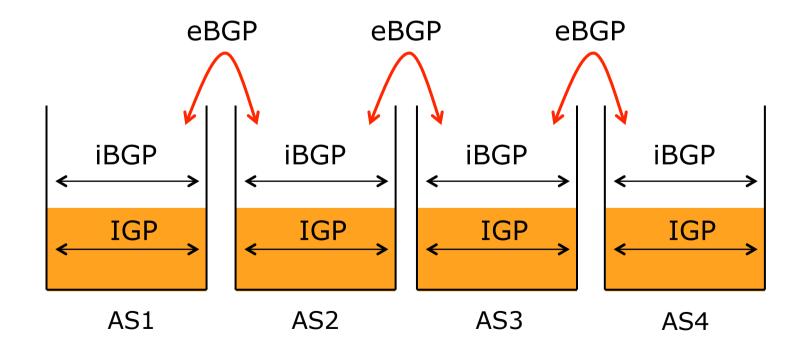

eBGP & iBGP

BGP is used

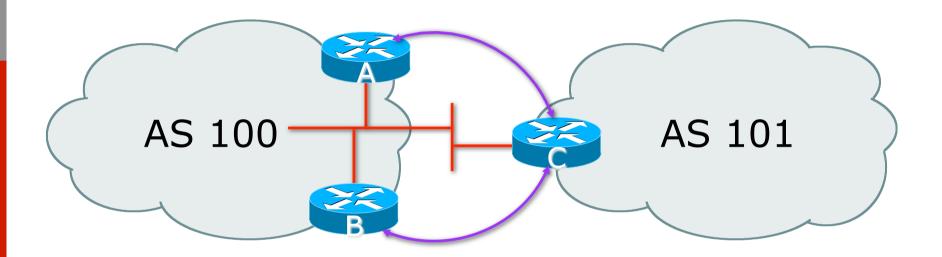

- Internally (iBGP)
- Externally (eBGP)
- IBGP used to carry
 - Some/all Internet prefixes across ISP backbone
 - ISP's customer prefixes
- eBGP used to
 - Exchange prefixes with other ASes
 - Implement routing policy

BGP/IGP model used in ISP networks

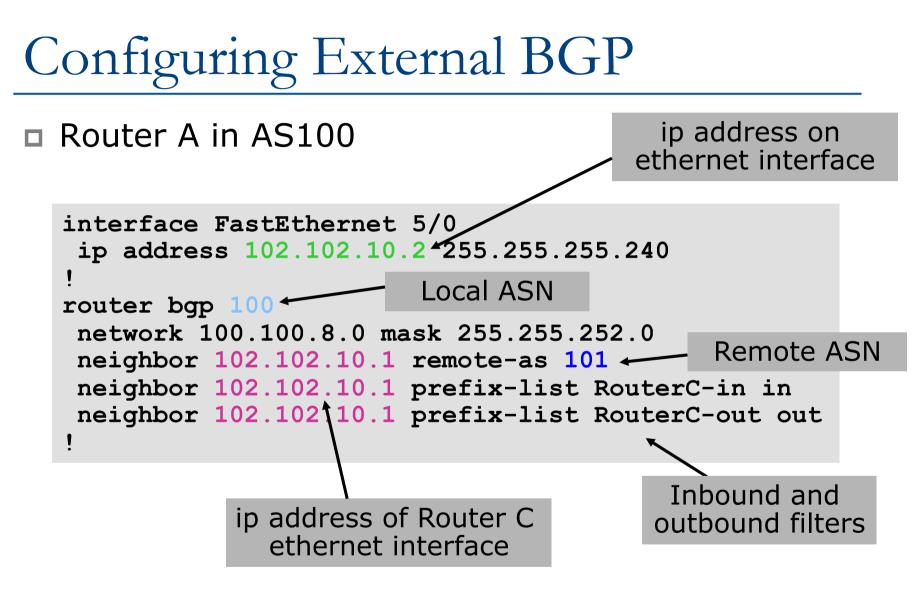

Model representation

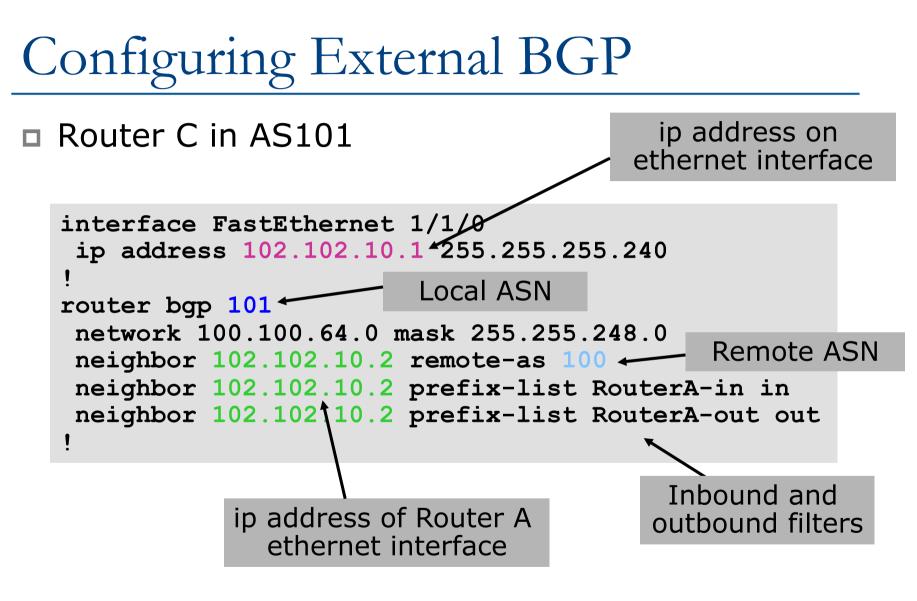

External BGP Peering (eBGP)

Between BGP speakers in different AS
 Should be directly connected
 Never run an IGP between eBGP peers

Internal BGP (iBGP)

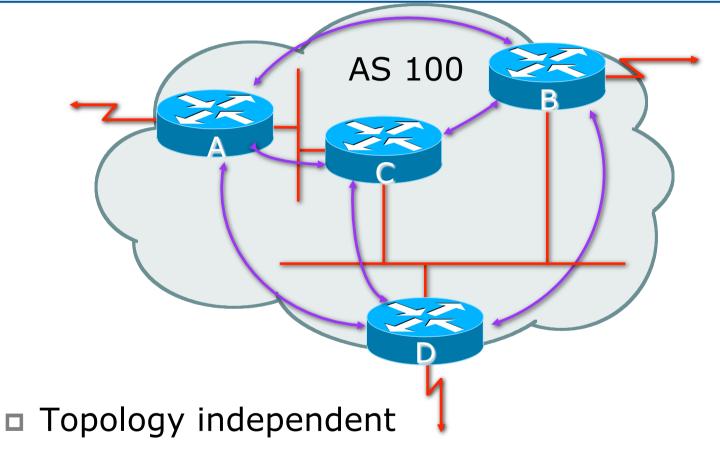

■ BGP peer within the same AS

- Not required to be directly connected
 - IGP takes care of inter-BGP speaker connectivity

■ iBGP speakers must be fully meshed:

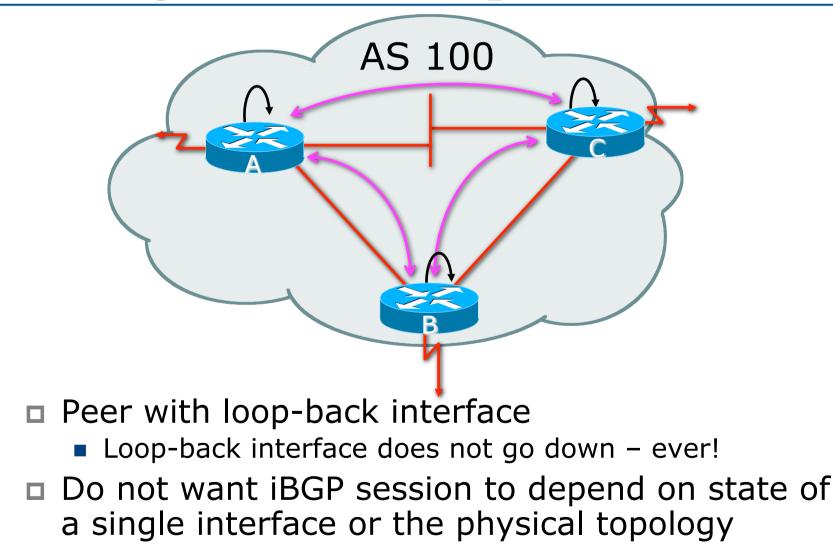

- They originate connected networks
- They pass on prefixes learned from outside the ASN
- They do not pass on prefixes learned from other iBGP speakers

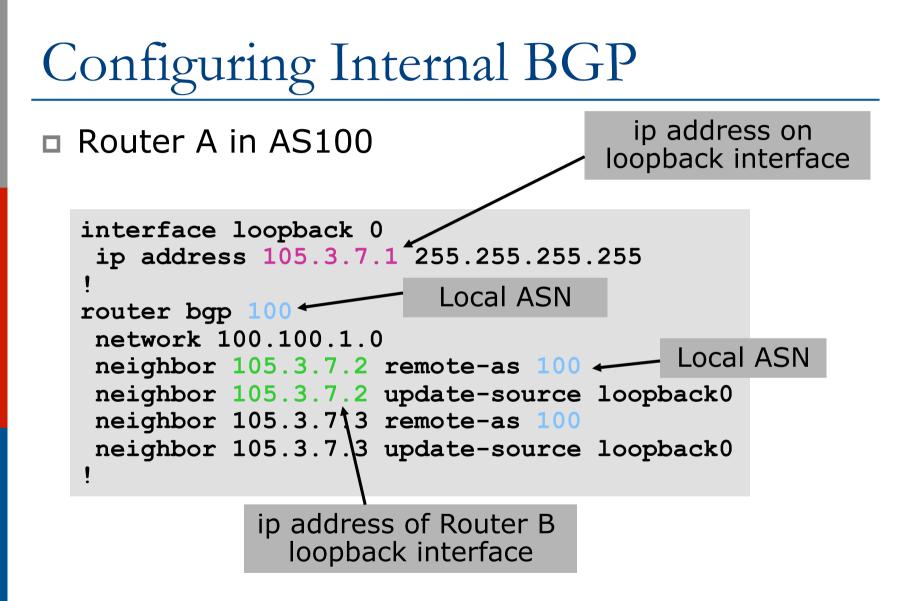

Internal BGP Peering (iBGP)

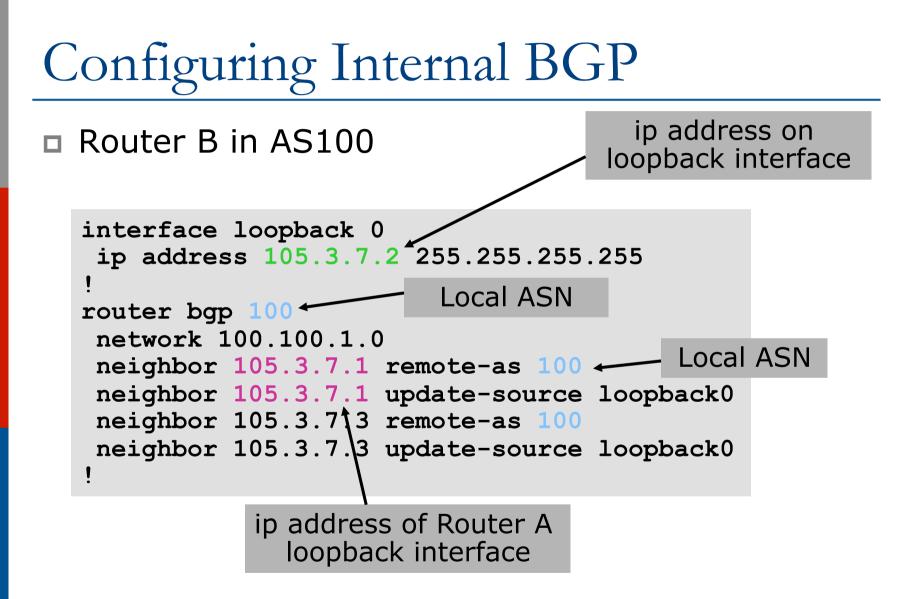

Each iBGP speaker must peer with every other iBGP speaker in the AS

Peering between Loopback Interfaces

Inserting prefixes into BGP

□ Two ways to insert prefixes into BGP

- redistribute static
- network command

Inserting prefixes into BGP – redistribute static

Configuration Example:

```
router bgp 100
redistribute static
ip route 102.10.32.0 255.255.254.0 serial0
```

Static route must exist before redistribute command will work
 Forces origin to be "incomplete"
 Care required!

Inserting prefixes into BGP – redistribute static

□ Care required with redistribute!

- redistribute <routing-protocol> means everything in the <routing-protocol> will be transferred into the current routing protocol
- Will not scale if uncontrolled
- Best avoided if at all possible
- redistribute normally used with "route-maps" and under tight administrative control

Inserting prefixes into BGP – network command

Configuration Example

```
router bgp 100
network 102.10.32.0 mask 255.255.254.0
ip route 102.10.32.0 255.255.254.0 serial0
```

 A matching route must exist in the routing table before the network is announced
 Forces origin to be "IGP"

Configuring Aggregation

Three ways to configure route aggregation

- redistribute static
- aggregate-address
- network command

Configuring Aggregation – Redistributing Static

Configuration Example:

```
router bgp 100
redistribute static
ip route 102.10.0.0 255.255.0.0 null0
```

Static route to "null0" is called a pull up route

- Packets only sent here if there is no more specific match in the routing table
- Care required see previously!

Configuring Aggregation – Network Command

Configuration Example

router bgp 100
network 102.10.0.0 mask 255.255.0.0
ip route 102.10.0.0 255.255.0.0 null0

A matching route must exist in the routing table before the network is announced
 Easiest and best way of generating an aggregate

Configuring Aggregation – aggregate-address command

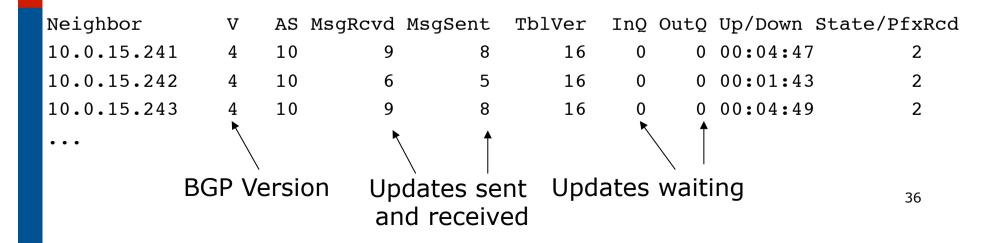

Configuration Example:

```
router bgp 100
network 102.10.32.0 mask 255.255.252.0
aggregate-address 102.10.0.0 255.255.0.0 [summary-only]
!
ip route 102.10.32.0 255.255.252.0 null 0
```

- Requires more specific prefix in BGP table before aggregate is announced
- summary-only keyword
 - Optional keyword which ensures that only the summary is announced (the more specific routes are suppressed)

Summary BGP neighbour status

Router6>sh ip bgp sum BGP router identifier 10.0.15.246, local AS number 10 BGP table version is 16, main routing table version 16 7 network entries using 819 bytes of memory 14 path entries using 728 bytes of memory 2/1 BGP path/bestpath attribute entries using 248 bytes of memory 0 BGP route-map cache entries using 0 bytes of memory 0 BGP filter-list cache entries using 0 bytes of memory BGP using 1795 total bytes of memory BGP activity 7/0 prefixes, 14/0 paths, scan interval 60 secs

Summary BGP Table

	Network	Next Hop	Metric	LocPrf	Weight	Path
*>i	10.0.0/26	10.0.15.241	0	100	0	i
*>i	10.0.0.64/26	10.0.15.242	0	100	0	i
*>i	10.0.0.128/26	10.0.15.243	0	100	0	i
*>i	10.0.0.192/26	10.0.15.244	0	100	0	i
*>i	10.0.1.0/26	10.0.15.245	0	100	0	i
*>	10.0.1.64/26	0.0.0	0		32768	i
*>i	10.0.1.128/26	10.0.15.247	0	100	0	i
*>i	10.0.1.192/26	10.0.15.248	0	100	0	i
*>i	10.0.2.0/26	10.0.15.249	0	100	0	i
*>i	10.0.2.64/26	10.0.15.250	0	100	0	i

37

Summary

BGP4 – path vector protocol
 iBGP versus eBGP
 Stable iBGP – peer with loopbacks
 Announcing prefixes & aggregates
